

Module 19: Spring MVC

CS544: Enterprise Architecture

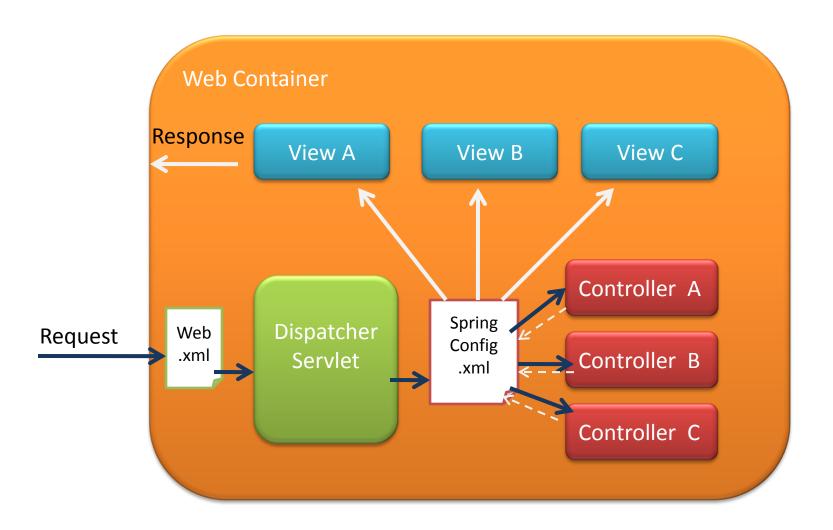

Spring MVC

- In this module we will look at the theory of how Spring MVC works, show a Spring MVC example.
 Spring MVC focuses on us having to do less, and accomplish more, by providing an extra layer of intelligence in between the technology and us.
- We will look at:
 - Application Context in a Web Container
 - Request Mapping
 - URI Templates
 - Data Input / Data Output
 - Session & Flash Attributes
 - Exception Handling

Spring MVC

- Spring MVC is a web development Framework that closely integrates with the rest of Spring (DI, AOP).
 - The jars for Spring MVC (web) are even included in the Core Spring download.
- Spring MVC is a request based web development framework that uses the front-controller pattern
 - Requests are first processed by the DispatcherServlet
 - After which they are mapped onto a handler method written by the programmer.
- Spring MVC is built on top of the Servlet API
 - All features of the Servlet API remain available

Front Controller / Dispatcher Servlet

Spring MVC:

BASIC EXAMPLE

Spring MVC Example – Web.xml

web.xml

</web-app>

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
xmlns="http://java.sun.com/xml/ns/javaee" xmlns:web="http://java.sun.com/xml/ns/javaee/web-
app 2 5.xsd" xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
http://java.sun.com/xml/ns/javaee/web-app 2 5.xsd" id="WebApp ID" version="2.5">
  <display-name>Example09.1</display-name>
  <servlet>
    <servlet-name>SpringMVC</servlet-name>
    <servlet-class>org.springframework.web.servlet.DispatcherServlet</servlet-class>
    <init-param>
      <param-name>contextConfigLocation</param-name>
      <param-value>/WEB-INF/springconfig.xml</param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
  </servlet>
  <servlet-mapping>
    <servlet-name>SpringMVC</servlet-name>
    <url-pattern>/</url-pattern>
  </servlet-mapping>
  <welcome-file-list>
    <welcome-file></welcome-file>
  </welcome-file-list>
```

Spring MVC – springconfig.xml

springconfig.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"</pre>
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:context="http://www.springframework.org/schema/context"
xmlns:mvc="http://www.springframework.org/schema/mvc"
xsi:schemaLocation="http://www.springframework.org/schema/beans
       http://www.springframework.org/schema/beans/spring-beans-3.0.xsd
       http://www.springframework.org/schema/context
       http://www.springframework.org/schema/context/spring-context-3.0.xsd
       http://www.springframework.org/schema/mvc
       http://www.springframework.org/schema/mvc/spring-mvc-3.0.xsd">
 <!- use @Controller annotations-->
 <mvc:annotation-driven />
 <!- scan for annotations in the following package -->
 <context:component-scan base-package="springmvc.helloworld" />
 <!-- Resolves views to .jsp resources in the /WEB-INF/views directory -->
 <bean class="org.springframework.web.servlet.view.InternalResourceViewResolver">
    cproperty name="viewClass" value="org.springframework.web.servlet.view.JstlView" />
    cproperty name="prefix" value="/WEB-INF/views/" />
    cproperty name="suffix" value=".jsp" />
  </bean>
</beans>
```

Spring MVC Basics – Controller

HelloWorld.java

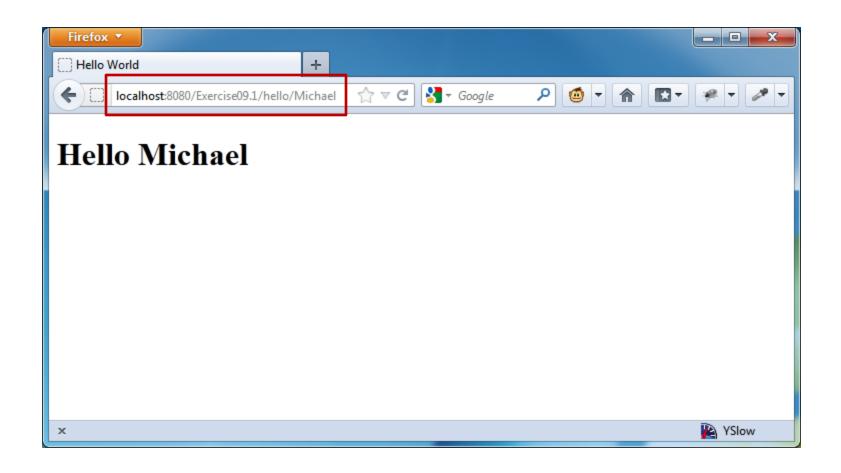

```
package springmvc.helloworld;
import org.springframework.stereotype.Controller;
import org.springframework.ui.Model;
import org.springframework.web.bind.annotation.PathVariable;
import org.springframework.web.bind.annotation.RequestMapping;
@Controller
public class HelloWorld {
 @RequestMapping("/hello/{name}")
  public String Hello(@PathVariable String name, Model model) {
    model.addAttribute("name", name);
    return "helloView";
```

Spring MVC Basics – View

helloView.jsp

```
<%@ page language="java" contentType="text/html; charset=UTF-8"</pre>
pageEncoding="UTF-8"%>
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1 Transitional//EN"</pre>
"http://www.w3.org/TR/xhtml1/DTD/xhtml11.dtd">
<html>
<head>
<meta http-equiv="Content-Type" content="text/html; charset=UTF-8">
<title>Hello World</title>
</head>
<body>
    <h1>Hello ${name}</h1>
</body>
</html>
```

Spring MVC Basics – Output

Spring MVC:

APPLICATION CONTEXT

Application Context

Optional Root

```
web.xml
```

```
Applcation
<?xml version="1.0" encoding="UTF-8"?>
                                                                                              Context
<web-app ...>
 <!-- The definition of the Root Spring Container shared by all Servlets and Filters -->
 <context-param>
    <param-name>contextConfigLocation</param-name>
   <param-value>/WEB-INF/spring/root-context.xml</param-value>
 </context-param>
 <! -- Creates/Starts the Root Spring Container shared by all Servlets and Filters -->
 <listener>
   <listener-class>org.springframework.web.context.ContextLoaderListener</listener-class>
 </listener>
 <!-- Creates the dispatcher servlet and its configuration -->
 <servlet>
    <servlet-name>spring</servlet-name>
   <servlet-class>org.springframework.web.servlet.DispatcherServlet</servlet-class>
    <init-param>
      <param-name>contextConfigLocation</param-name>
      <param-value>/WEB-INF/spring/dispatcher-context.xml</param-value>
                                                                                     Optional, defaults to:
    </init-param>
                                                                                   [servlet-name]-servlet.xml
    <load-on-startup>1</load-on-startup>
 </servlet>
 <servlet-mapping> <!-- Maps the dispatcher servlet to all requests in this project -->
    <servlet-name>spring</servlet-name>
    <url-pattern>/</url-pattern>
 </servlet-mapping>
                                                                                                 12
</web-app>
```

Minimal web.xml

web.xml

No root context, or dispatcher context specified

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
xmlns="http://java.sun.com/xml/ns/javaee" xmlns:web="http://java.sun.com/xml/ns/javaee/web-
app 2 5.xsd" xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
http://java.sun.com/xml/ns/javaee/web-app 2 5.xsd" id="WebApp ID" version="2.5">
  <servlet>
    <servlet-name>min-example</servlet-name>
    <servlet-class>org.springframework.web.servlet.DispatcherServlet</servlet-class>
    <load-on-startup>1</load-on-startup>
  </servlet>
                                                              Will look for default config:
  <servlet-mapping>
                                                          /WEB-INF/min-example-servlet.xml
    <servlet-name>min-example</servlet-name>
    <url-pattern>/</url-pattern>
  </servlet-mapping>
  <welcome-file-list>
    <welcome-file></welcome-file>
  </welcome-file-list>
</web-app>
```

Spring MVC:

REQUEST MAPPING

Request Mapping by Path

```
@Controller
public class CarController {
                                           All requests for the path
                                           "/cars" will be mapped
                                             onto this method
  @RequestMapping(value="/cars")
  public String getAll(Model model) {
    model.addAttribute("cars", carDao.getAll());
    return "carList";
```

Request Mapping by HTTP Method

```
@Controller
public class CarController {
                                                               Requests for "/cars" using
                                                               a GET will be mapped to
                                                                the getAll() method
  @RequestMapping(value="/cars", method=RequestMethod.GET)
  public String getAll(Model model) {
    model.addAttribute("cars", carDao.getAll());
                                                               Requests for "/cars" using
    return "carList";
                                                               a POST will be mapped to
                                                                  the add() method
  @RequestMapping(value="/cars", method=RequestMethod.POST)
  public String add(Car car) {
    carDao.add(car);
    return "redirect:/cars";
```

Class Level Path Mapping

```
@Controller
public class CarController {

@RequestMapping(value="/cars/{id}", method=RequestMethod.GET)
public String get(@PathVariable int id, Model model) {
    model.addAttribute("car", carDao.get(id));
    return "carDetail";
}

@RequestMapping(value="/cars/{id}", method=RequestMethod.POST)
public String update(Car car, @PathVariable int id) {
    carDao.update(id, car);
    return "redirect:/cars";
}

@Controller
@RequestMapping(value="/cars")
```

Exactly the same as

```
@RequestMapping(value="/cars")
public class CarController {

    @RequestMapping(value="/{id}", method=RequestMethod.GET)
    public String get(@PathVariable int id, Model model) {
        model.addAttribute("car", carDao.get(id));
        return "carDetail";
    }

    @RequestMapping(value="/{id}", method=RequestMethod.POST)
    public String update(Car car, @PathVariable int id) {
        carDao.update(id, car);
        return "redirect:/cars";
    }
}
```

Web Services

Produces & Consumes

```
@Controller
public class WebServiceController {
                                                                If the client is expecting text/xml content
                                                                    (indicated by Accepts header)
  @RequestMapping(value="/list", method=RequestMethod.GET, produces="text/xml")
  public ModelAndView list() {
    ModelAndView mav = new ModelAndView();
    mav.setViewName("marshalview");
    mav.addObject("list", shoppingListService.getList());
                                                                   If the client is passing in text/xml content
    return mav;
                                                                     (indicated by Content-Type header)
  @RequestMapping(value = "/list", method = RequestMethod.POST, consumes="text/xml")
  public RedirectView addItem(@RequestBody Item item) {
    shoppingListService.addToList(item);
    return new RedirectView("list");
```

Parameters and Headers

```
@Controller
public class CarController {
                                                             Only requests for
                                 params="myParam" or
                                                          "/cars?myParam=myvalue"
                                                            will be mapped here
                                 params="!myParam"
                                    also possible
  @RequestMapping(value="/cars", params="myParam=myValue")
  public String getAll(Model model) {
    model.addAttribute("cars", carDao.getAll());
                                                                 Only Requests that have
    return "carList";
                                                                   an http header:
                                                                  myHeader: myValue
                                                                  Will be mapped here
 @RequestMapping(value="/cars", headers="myHeader=myValue")
  public String getAll(Model model) {
    model.addAttribute("cars", carDao.getAll());
    return "carList";
```

Mapping to non-Controllers

Static content (html / css / js)
Or a view without controller

springconfig.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<beans ...>
  <!-- Maps '/' requests to the 'home' view -->
  <mvc:view-controller path="/" view-name="home"/>
  <!-- Handles HTTP GET requests for /resources/** by efficiently serving
      up static resources in the ${webappRoot}/resources/ directory -->
 <mvc:resources mapping="/resources/**" location="/resources/" />
 <!-- Lets us find resources (static and dynamic) through the web.xml -->
  <mvc:default-servlet-handler/>
</beans>
```

AOP & Request Mapping

- When using proxies:
 - Place @RequestMapping on interface
 - The proxy will need to have mappings as well

E.g. when using @Transactional in your controller

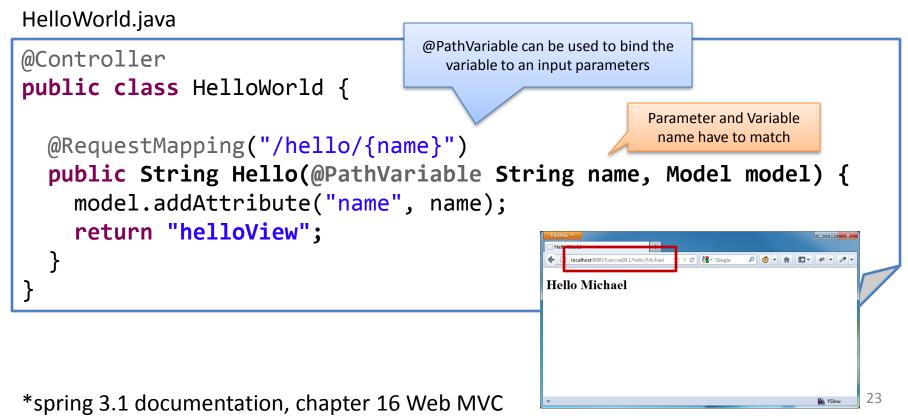

- Unless you're using CGLIB subclass proxies
 - By default Spring uses JDK dynamic proxies that require an interface

Spring MVC:

URI TEMPLATES

URI Templates

 A URI Template is a URI-like string, containing one or more variable names. When you substitute values for these variables, the template becomes a URI.*

Multiple Variables

```
@Controller
public class CustomerController {
  @RequestMapping(value="/customer/{customerId}/order/{orderId}")
  public String getOrder(@PathVariable long customerId,
                       @PathVariable long orderId, Model model) {
    // implementation ...
                                                   Either directly on the method level, or
                                                     combined from class and method
@Controller
@RequestMapping(value="/customer/{customerId}")
public class CustomerController {
  @RequestMapping(value="/order/{orderId}")
  public String getOrder(@PathVariable long customerId,
                       @PathVariable long orderId, Model model) {
    // implementation
```

Regex and Path Patterns

```
// Regular Expression Matching
@RequestMapping(value="/email/{user:\w+}@{host:\w+}.{tld:\w+}")
public void getInfo(@PathVariable String user,
           @PathVariable String host, @PathVariable String tld) {
  // implementation ...
// Ant-Style path patterns
@RequestMapping(value="/customer/*/order/{orderId}")
public void getOrder(@PathVariable long orderId, Model model) {
  // implementation ...
```

Spring MVC:

DATA INPUT

Request Input

We've seen how path variables can be used for input

GET /cars/1

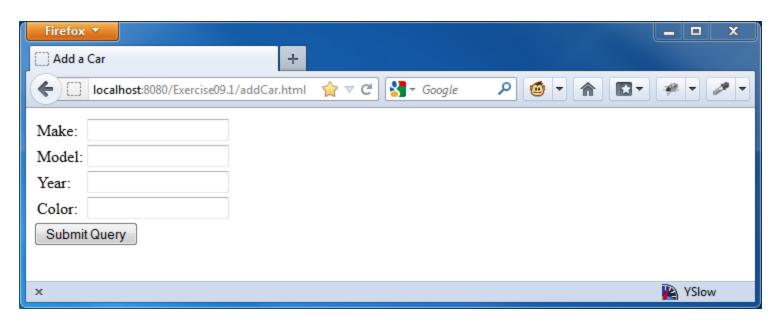

```
@RequestMapping(value="/cars/{id}", method=RequestMethod.GET)
public String get(@PathVariable int id, Model model) {
   model.addAttribute("car", carDao.get(id));
   return "carDetail";
}
```

But the same can of course be done with normal request parameters

params specification is optional!

GET /cars?id=1

Many Parameters

```
public class Car {
  private int id;
  private String make;
  private String model;
  private int year;
  private String color;
```

Do Less and Accomplish More

```
@RequestMapping(value="/cars", method=RequestMethod.POST)
public String addParams(String make, String model, int year, String color) {
   Car car = new Car(make, model, year, color);
   carDao.add(car);
   return "redirect:/cars";
}

You can receive the form
parameters and combine them
into a Car object yourself
```

But you may as well have Spring do all the work for you

Additional Parameters

The following objects can be passed into Methods:

@PathVariable HttpServletRequest

@RequestParam HttpServletResponse

@RequestHeader HttpSession

@RequestBody InputStream

@RequestPart (file upload)
OutputStream

Map / Model / ModelMap Reader

BindingResult / Errors Writer

SessionStatus Principal (security)

RedirectAttributes Locale (internationalization)

- You can also define your own custom injectors
 - See Spring documentation

Spring MVC:

DATA OUTPUT

Data Output

- There are two main ways to output data:
 - Render a view

- Several ways to specify view name
- Providing it 'Model' data
- Output an object

- Use @ResponseBody on return type
- Use message converters transforms to desired format
- View name can be used to specify transformer

Return String View Name

springconfig.xml

CarController.java

What is the name of our view? / Where will Spring MVC look for it?

View

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1 Transitional//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml11.dtd">
<html>
<head><title>Add a Car</title></head>
<body>
 <form action="../cars/${car.id}" method="post">
 >
    Make:
    <input type="text" name="make" value="${car.make}" /> 
   Model:
    <input type="text" name="model" value="${car.model}" /> 
  Year:
    >
    Color:
    <input type="text" name="color" value="${car.color}" /> 
  <input type="submit" value="update"/>
 </form>
 <form action="delete?carId=${car.id}" method="post">
  <button type="submit">Delete</button>
 </form>
</body>
</html>
```

ModelAndView

springconfig.xml

CarController.java

Implicit View Name

- You can omit (not specify) a view name
 - Spring uses convention over configuration
 - Convention: convert the request url to view name

DispatcherServlet will instantiate an instance of this bean if one is not explicitly configured thereby providing convention over configuration

springconfig.xml

CarController.java

```
@RequestMapping(value="/cars", method=RequestMethod.GET)
public void getAll(Model model) {
   model.addAttribute("cars", carDao.getAll());
}
No View Name given
anywhere
```

Redirects

- Redirects are important!
 - After processing (POST) input -> always redirect
 - Known as Post/Redirect/Get Pattern*
 - Separation of concerns
 - No problems with refresh
 - No duplicate submissions

^{*}See: http://en.wikipedia.org/wiki/Post/Redirect/Get

Redirects

checks Model for data

ListController.java

```
@RequestMapping(value = "/list", method = RequestMethod.POST)
public RedirectView addItem(@RequestBody Item item)
{
    shoppingListService.addToList(item);
    return new RedirectView("list");
}
Pre Spring 3
```

Spring MVC:

SESSION & FLASH ATTRIBUTES

HttpSession

 If you want you can have direct access to the HttpSession, by requesting it as an additional parameter

- Not very elegant ⊕

CarController.java

@RequestMapping(value="/cars/session")

public @ResponseBody String session(HttpSession session) {

Enumeration<String> attributes = session.getAttributeNames();

StringBuilder output = new StringBuilder();

while (attributes.hasMoreElements()) {

output.append(attributes.nextElement());

output.append(" ");

}

return output.toString();

}

@SessionAttributes

- @Controller can specify @SessionAttributes
 - Intended for the duration of controller

Like Checkout or Authentication Controller

- lists the names of model attributes which should be transparently stored in the session
 - Once the specified attributes are added to the model, they are kept in the model
 - Achieved by Spring storing them in the session

CarController.java

```
@Controller
@SessionAttributes(value={"cars", "currentId"})
public class CarController {
    ...
}
```

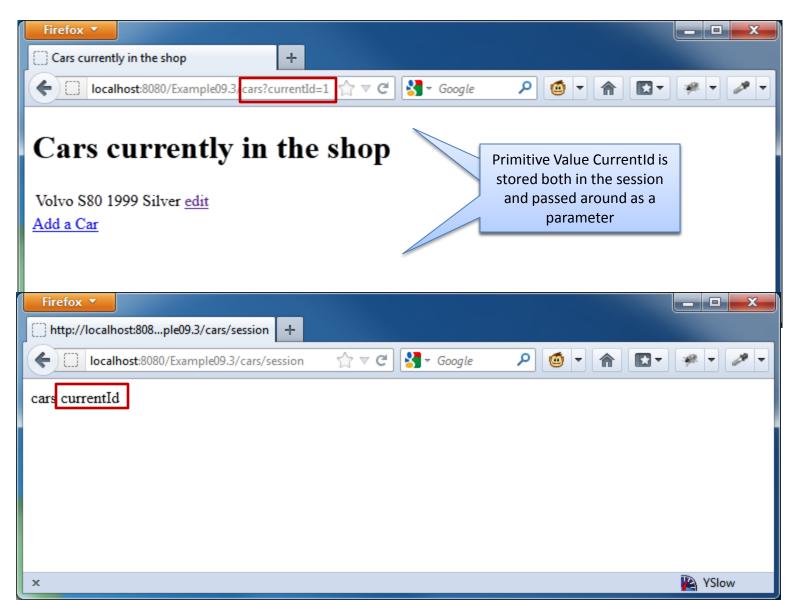

Transparently Stored

```
@Controller
@SessionAttributes(value={"cars", "currentId"})
                                                         Method never explicitly uses
public class CarController {
                                                              HttpSession
  @RequestMapping(value="/cars", method=RequestMethod.POST)
  public String add(Car car, ModelMap m) {
                                                          Does not exist in model on
    if (!m.containsAttribute("cars")) {
                                                          first request, so we add
      System.out.println("No Cars List Yet");
      m.addAttribute("cars", new ArrayList<Car>());
      m.addAttribute("currentId", 0);
                                                           Already in model on
    } else {
                                                          subsequent requests
      int id = (Integer)m.get("currentId");
      System.out.println("Cars List Exists, currentId: " + id);
    List<Car> cars = (List<Car>)m.get("cars");
    cars.add(car);
    Integer currentId = (Integer) m.get("currentId");
    m.put("currentId", currentId + 1);
    return "redirect:/cars";
```

Removed on Completion

```
@Controller
@SessionAttributes(value={"cars", "currentId"})
public class CarController {
                                             SessionStatus additional
                                                 parameter
  @RequestMapping(value="/cars/clear")
  public String clear(SessionStatus status) {
    // clears SessionAttributes specified on classlevel
    status.setComplete();
    return "redirect:/cars";
```

Interesting Side Effect

New in Spring 3.1

Flash Attributes

- Flash attributes provide a way for one request to store attributes intended for use in another.
- This is most commonly needed when redirecting —
 for example, the Post/Redirect/Get pattern.
- Flash attributes are saved temporarily before the redirect (typically in the session) to be made available to the request after the redirect and removed immediately.*

*From: http://static.springsource.org/spring/docs/3.1.x/spring-framework-reference/html/mvc.html#mvc-flash-attributes

'next' request

Specifying Flash Attributes

CarController.java

```
@Controller
public class CarController {

@RequestMapping(value="/cars", method=RequestMethod.POST)
public String add(Car car, RedirectAttributes redirectAttrs) {
    carDao.add(car);
    String msg = "Added " + car.getMake() + " " + car.getModel();
    redirectAttrs.addFlashAttribute("message", msg);
    return "redirect:/cars";
}

Make sure you use the
addFlashAttribute() method,
not the addAttribute() method)

Not the addAttribute() method)
RedirectAttributes
additional parameter

RedirectAttributes
additional parameter
```

Receiving Flash Attributes

```
CarController.java
                                    Received Flash Attributes
                                                            Whether your method
                                    are automatically added to
                                                             requests a Model
@Controller
                                         the Model
                                                              parameter or not
public class CarController {
  @RequestMapping(value="/cars", method=RequestMethod.GET)
  public String getAll(ModelMap model) {
    if (model.containsAttribute("message")) {
       System.out.println("Message: " + model.get("message"));
    } else {
       System.out.println("No Message");
                                                         This code was written for
                                                        demonstrative purposes only
    model.addAttribute("cars", carDao.getAll());
    return "carList";
```

Using Flash Attributes

```
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" %>
<%@ page language="java" contentType="text/html; charset=UTF-8"</pre>
pageEncoding="UTF-8"%>
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1 Transitional//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml11.dtd">
<html>
<head>
  <meta http-equiv="Content-Type" content="text/html; charset=UTF-8">
 <title>Cars currently in the shop</title>
</head>
<body>
 <h1>Cars currently in the shop</h1>
  <c:forEach var="car" items="${cars}">
   >
     ${car.make}
     ${car.model}
     ${car.year}
     ${car.color}
     <a href="cars/${car.id}">edit</a>
   </c:forEach>
  If a flash attribute is passed
 <c:if test="${not empty message}">
                                                       in, it will be available
   Message: <strong>${message}</strong>
                                                      during view rendering
 </c:if>
  <a href="addCar.html"> Add a Car</a>
</body>
```

</html>

Spring MVC:

EXCEPTION HANDLING

Exception Handling

- @Controller level
 - Annotate methods with @ExceptionHandler

- Dispatcher Servlet Config
 - DefaultHandlerExceptoinResolver
 - Maps common exceptions to appropriate status codes
 - Add Custom HandlerExceptionResolver as needed

Exception Handling

CarController.java

```
@ExceptionHandler(value=NoSuchResourceException.class)
public ModelAndView handle(Exception e) {
   ModelAndView mav = new ModelAndView();
   mav.addObject("e", e);
   mav.setViewName("noSuchResource");
   return mav;
}
```

Active Learning

 What are the different ways that the view can be specified?

 Why is it generally not necessary to redirect GET requests?

Summary

- We've discussed:
 - The application context in a web container
 - Spring MVC Request Mapping
 - URI templates
 - Data input / Data Output
 - Sessions & Flash Attributes
 - Exception Handling

There is a lot to SpringMVC, but at it's core it is a request centric web framework with URI templates. Providing an extra layer that allows us to do less, and accomplish more.
